Attention compares the word's meaning but has no built-in sense of sequence.

The key idea

- Before words enter the stack, each position has its own unique vector of 512 dimensions.
- The embedding of a word is added to the position vector/stamp of its position.

This works because 512 dimensions have alot of room to store information. And position stamps follow a fixed, regular pattern where the layers above can separate out the position part if needed.
